

1 Introduction

The aim of this work is to estimate the parameters of the SIR model. In particular, I will focus on the first wave of contagion of the Coronavirus pandemic in Italy.

Figure 1: New infections per day in Italy

2 Model & Estimation

The model is as follows:

$$N_t = \gamma_1 N_{t-1} + \gamma_2 N_{t-1} \ln N_{t-1} + U_t, \quad (1)$$

where N_t is the total infected population at time t , and U_t is the error term.

The model has been estimated through GMM, using the following instruments (which are assumed to be exogenous with respect to U_t):

- N_{t-1}
- $N_{t-1} \ln N_{t-1}$
- Daily average temperature in Italy (not used in Model 1, but used in Model 2)
- Daily average mobility in Italy, in particular the percent change from baseline of occupation of:
 - Retail and recreation facilities
 - Transit stations

The results are as follows:

| | Model 1 | Model 2 |
|--------------|-------------------------|-------------------------|
| γ_1 | 1.720*** (0.0204) | 1.718*** (0.0201) |
| γ_2 | -0.0582*** (0.00166) | -0.0579*** (0.00163) |
| Observations | 136 | 136 |
| J-stat | 12.48 | 13.08 |
| DoF | 1 | 2 |

Table 1: GMM results: standard errors are in parentheses and $*p < 0.10$, $**p < 0.05$, $***p < 0.01$

3 Explicit Solution

In continuous time, the model equation (1) admits the following close form solution (i.e. total cases):

$$N(t) = \exp\left(\frac{K e^{\gamma_2 t} - \gamma_1 + 1}{\gamma_2}\right), \quad K = \gamma_1 + \gamma_2 \ln N_0, \quad (2)$$

And derivative (i.e. new cases):

$$\dot{N}(t) = K e^{\gamma_2 t} N(t). \quad (3)$$

K can therefore be estimated, in this case, I used grid search to find:

$$\hat{K} = \arg \min_K \|N_t - \hat{N}_K(t)\|, \quad \hat{K} = 0.5175 \quad (4)$$
